

## SCHEMA DESIGN

May 2017

Dave Kemp

-- NSA, Cybersecurity Architecture and Strategies

# Status

2

- Updates since Sept 2016 Forum face-to-face:
  - ▣ **Implementation:** Python classes --> JAEN document
    - Test-driven design, full suite of unit tests using example data
    - Encoder methods
    - JSON-minified serialization format
    - Flattened API supports dicts and arrays
  - ▣ **Targets:** CybOX 2.1 --> streamlined STIX Cyber Observables
    - Attribute {"type": "ipv4", "value": "1.2.3.4"}  
--> Property {"ipv4": "1.2.3.4"}
  - ▣ **Response:** action --> separate datatype
  - ▣ **Modifiers:** refactored

# Purpose: Interoperability

3

- Schema serves two independent purposes:
  - ▣ Message Definition and Validation
    - Unambiguous specification
    - Required even without serialization
  - ▣ Message Serialization
    - API / JSON – standard, human readable, ensures interoperability
    - Optional Transformations: (JSON-Minified, Binary) – allows performance optimization if supported by both sender and receiver

# Message Definition and Validation

4

## □ Database: SQL vs NoSQL

- NoSQL databases are built to allow the insertion of data without a predefined schema. Developers have typically had to add application-side code to enforce data quality controls, such as mandating the presence of specific fields, data types or permissible values.

--- “NoSQL Databases Explained”, <https://www.mongodb.com/nosql-explained>

- SQL query is just text. NoSQL models require coding in some language.
  - “The more the DB engine knows about the Data Model, the more it can do for you”
- Best practice: use right tool for the job – SQL \*and\* NoSQL

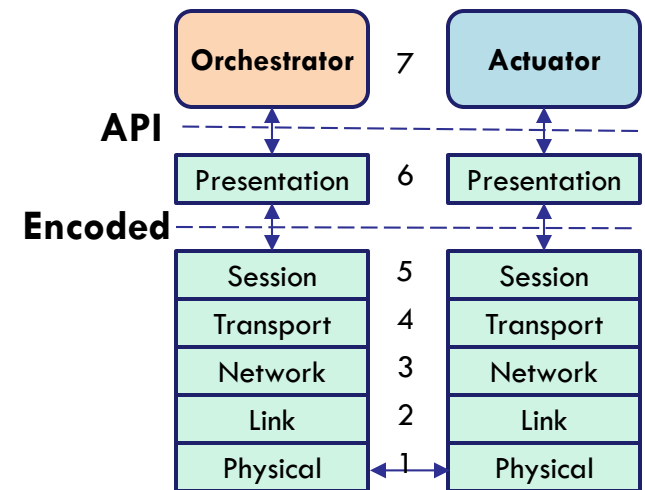

## □ Protocol data models: Schema vs. Property tables

- No schema: Validation requires program coding, updates require re-coding
- Schema is just text: Codec/validation engine doesn’t change when protocol is updated

# Message Serialization

5

- Serialization is a network layer six function:
  - ▣ “The Presentation layer provides independence from data representation by translating between **application** and **network** formats.” -- Wikipedia
  - ▣ **application**: “state of an object instance” in a program
- Codec is application-independent
  - ▣ Implemented as a library called by applications (as with compression, signature, encryption)
  - ▣ Internet Text Messages (RFC 822) / MIME Internet Message Bodies (RFC 2045) define e-mail application payload
  - ▣ ZLIB (RFC 1950), S-MIME (RFC 5751) define Presentation-Layer transformations of payload
  - ▣ Existence of transformations **does not** create e-mail application incompatibility
- There is only one OpenC2 API
  - ▣ Define schema-based transformations in separate document

# Bandwidth Optimization

6

Example	JSON-Verbose*	JSON-Minified	Compressed**
T1_mitigate	77	30	164
T2_contain	170	88	216
T3_deny	390	190	351
T6_update	359	222	335

Message size in bytes

\*No whitespace

\*\*WinRAR compression

<https://github.com/OpenC2-org/jaen/tree/master/examples>

Schema-based optimization is more effective than compression for small messages

# Web Optimization – a standard practice

7

## Verbose – human readable

```

( function( global, factory ) {

    "use strict";

    if ( typeof module === "object" && typeof module.exports === "object" ) {

        // For CommonJS and CommonJS-like environments where a proper `window`
        // is present, execute the factory and get jQuery.
        // For environments that do not have a `window` with a `document`
        // (such as Node.js), expose a factory as module.exports.
        // This accentuates the need for the creation of a real `window`.
        // e.g. var jQuery = require("jquery")(window);
        // See ticket #14549 for more info.
        module.exports = global.document ?
            factory( global, true ) :
            function( w ) {
                if ( !w.document ) {
                    // For browser-like environments, create a document
                    // and pass it to the factory function.
                    w.document = document;
                }
                return factory( w, true );
            };
    } else {
        factory( global, false );
    }
} );

# Auto-generated Property Tables (cont.)

11

- JAEN is not a mysterious foreign language
  - ▣ Machine-readable (JSON)
  - ▣ Constrained content
    - Represents a valid schema (verifiable)
    - Structured text (but description field is free-form)
  - ▣ Directly representable in property table format
    - By design

# MRPT

# Schema Design and Use (hand-coding)

13

# OpenC2 Message Definition

14

- STIX: Standard contains property tables and JSON examples
  - ▣ Property tables are *normative* but *not testable*
  - ▣ Member-developed JSON Schemas are testable but are not part of the STIX standard
  - ▣ No path to efficient message encoding for production systems
  
- OpenC2: Standard contains schema and examples
  - ▣ Abstract schema is *normative* and *testable*
  - ▣ Property tables are auto-generated from normative schema
  - ▣ Member-developed concrete schemas (JSON and Binary) are derived from abstract schema and are testable
    - Goal: auto-generation of concrete schemas from abstract schema
  - ▣ Examples have been validated against normative schema

# Who uses schemas?

15

## Data Serialization:

- Apache Avro
- JAEN

## Messaging:

- Apache Kafka
- OpenDXL

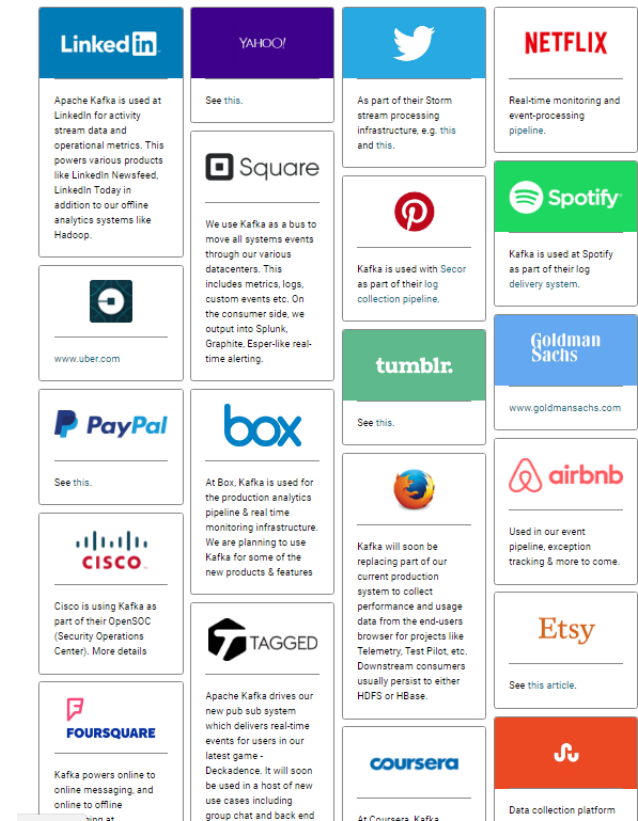

“Though Kafka itself is serialization-agnostic, LinkedIn has standardized on the use of Apache Avro as the schema and serialization language for all of its activity data messages as well as data in Hadoop and most other data systems. In uncompressed form our Avro data was roughly 7 times smaller than XML messages in the activity logging system we replaced.”

“This pipeline currently runs in production at LinkedIn and handles more than 10 billion message writes each day with a sustained peak of over 172,000 messages per second.”

“Building LinkedIn’s Real-time Activity Data Pipeline”

<http://sites.computer.org/debull/A12june/pipeline.pdf>

<https://kafka.apache.org/powered-by>

# OpenC2 Design Choices

16

“Avro specifies two serialization encodings: binary and JSON. Most applications will use the binary encoding, as it is smaller and faster. But, for debugging and web-based applications, the JSON encoding may sometimes be appropriate.”

--- <https://avro.apache.org/docs/current/spec.html>

- Avro is widely deployed, why create JAEN?
  - ▣ Direct correspondence with STIX property tables
  - ▣ Avro schemas are mandatory; JAEN interoperates with schema-less implementations
  - ▣ Multiple JSON encodings
    - JSON-minified is an efficient text-based alternative to binary
  - ▣ More flexible reverse-engineered abstract schemas?
    - Difficulty of specifying some existing JSON datatypes (e.g., ATVs) in Avro is unknown
- Way forward:
  - ▣ Short term – add Avro capabilities to JAEN, harmonize nomenclature
    - Namespaces, binary encoding, fixed datatypes, ...
  - ▣ Mid term – Switch OpenC2 normative schema to Avro or CDDL if feasible
    - Would require property table generation

# Getting Started

17

- Install JAEN software
  - ▣ <https://github.com/OpenC2-org/jaen>
- Run example\_app
- View and run unit test files
  - ▣ Comprehensive examples for using and testing the JAEN codec
- If schema is modified:
  - ▣ Run jaen\_convert to generate derived schemas
  - ▣ Re-run unit tests to generate example messages

## Getting Started

1. Use a Python 3 environment. Install the jsonschema (for the codec) and XlsxWriter (for the converter property table generator) packages if not already installed. This software was developed under Python 3.3-3.5 and is not yet ported to Python 2.x.
2. Look at the `examples` folder for example OpenC2 commands in JSON format. These files are generated automatically by the `test_openc2.py` unit test.
3. An OpenC2 producer application would create a python dict containing an OpenC2 command, load the `openc2jaen` schema, and encode the command:

```
import json
from jaen.codec.codec import Codec
from jaen.codec.jaen import jaen_load

command = {
    "action": "mitigate",
    "target": {
        "domain_name": {
            "value": "cdn.badco.org"
        }
    }
}

schema = jaen_load("openc2.jaen")
codec = Codec(schema, verbose_rec=True, verbose_str=True)
message1 = codec.encode("OpenC2Command", command)
print("Sent Message =", json.dumps(message1))
```

# Load and validate the OpenC2 schema  
# Create an OpenC2 encoder/decoder (JSON-Verbose encoding)  
# Validate and encode the command

# FAQ

18

Q: If targets have no “type” property, how does one find their type?

A: Mapping types (Python dicts, JSON objects) are collections of key: value pairs. When an object has only one item, the key is the type of that item.

Attribute:      `target = {"type": "ipv4", "value": "1.2.3.4"}`  
                  `type = target["type"]`

Property:        `target = {"ipv4": "1.2.3.4"}`  
                  `for key in target: type = key`

-- or --

`type = next(iter(target))`

BACKUP
